Gender Issues Related to the use of Groundwater Irrigation Technologies

The Upper East Region (UER) is one of the poorest areas in Ghana. The area is semi-arid and the population mainly depends on subsistence agriculture. Increasing market demand for vegetables in the urban centers of southern Ghana, within the past 15 years, has triggered the farmer-initiated introduction of groundwater irrigation technologies, such as temporal and permanent shallow wells and riverine alluvial dugouts for dry-season irrigation. Yet, identifying the linkages between irrigation, food production and poverty alleviation for all local stakeholders requires a clear understanding of how men and women contribute to and are affected by irrigation development. The International Water Management Institute (IWMI) examined...
the gender dimensions of participation in the use of three groundwater irrigation technologies and in decision-making. It assessed how social relationships shape opportunities for the control of resources and investments and the sharing of costs and benefits. Important factors determining who can and who cannot participate and profit from irrigation are rights to land and water, inheritance, local leadership, intra-household relationships, credit and market conditions (INPIM 2007).

The focused on two communities where the use of groundwater for irrigation was prevalent:

1. Anateam in Bolgatanga District, where riverine alluvial dugouts (RADs) and temporal shallow wells (TSWs) are predominant.

2. Telenea in Kasena-Nankana District, where permanent shallow wells (PSWs) and TSWs are predominant.

Field methodologies for data collection were as follows:

1. Focus group discussion with men and women farmer irrigators
2. Field survey with women farmers
3. Key informant interviews with village chiefs
4. Regional workshop to get feedback from stakeholders from four districts (Bolgatanga, Bongo, Kasena-Nankana and Kasena-Nankana East) in the study area, with representatives from district assemblies, the Water Resources Commission, and NGOs involved in irrigation development (e.g., Red Cross).

Gender dimensions in groundwater irrigation technologies: Some highlights

Land and water rights

There is a multitude of extremely complex land tenure and management systems in Ghana (Kasanga and Kotey 2001). There are more than 80 formal legal instruments regulating land tenure, some of which are contradictory. They co-exist with various forms of customary land tenure. For instance, the tribes in the study areas within northern Ghana believe that land is held in sacred trust for the ancestors. To them, selling their land is a sacrilege. Farm households are allocated ‘family
Gender Issues Related to the use of Groundwater Irrigation Technologies

they can request land from the tendana (Birner et al. 2005). The usufruct rights can be passed on to the descendants by inheritance so that land tenure is secure for as long as the land is cropped. When the land is fallow, the tendana can redistribute it. A tendana is an established local authority, such as a priest or a village chief, responsible for looking at land issues. A part of the farmers’ harvest is given to him as rent, in recognition of his authority.

Usufruct rights have considerable social implications. Unless the occupier of the land stands in breach of the chief or the tendana, he cannot be deprived of his usufruct rights.

The increase in population density tends to decrease available land for the growing population. Smaller households, which do not have enough labor to cultivate their own land, can lease part of their land to their neighbors or relatives. Land security is assured for usufruct rights holders, though not for migrant farmers.

Land rights are linked to water rights. A person who holds the rights to a plot of land is allowed to tap groundwater beneath that plot of land (Lentz 2006). Surface water, however, is considered a communal resource that is freely and openly accessed, in adherence to communal water use rules (FAO 1998, Ministry of Works and Housing 1998).

Access to land and water

It is customary in the UER to consider inheritance of land as patrilineal and the traditional laws do not recognize usufruct rights for females. Women have only indirect land rights—they access land through a male member of the family. The only exception is if a household is headed by a female, in which case, they can request land from the tendana (Birner et al. 2005). Typically, women can temporarily use their husband’s land. Unmarried women seldom have access to land, and widows lose access unless they have male children. Women with resources can rent land to farm. However, women are usually given small plots that are farthest from water sources or are least productive (IFAD 1998).

women are more reliable rent payers. Women who are interested in renting land have to negotiate through their husbands, while female heads of families and unmarried women hire laborers. Some women were eligible to negotiate for engagement in dry-season farming have been successful.

Women and children learn how to irrigate and manage their own plots by working as laborers in the plots owned by their male head of household. Children take over when the women are away and assist in digging wells and watering. Enterprising women hire young men to help with the digging, irrigating and weeding.

In a mixed system, husbands support the women during land cultivation and provide protection from grazing livestock. At times, they have to depend on their neighbors, children or hired laborers to secure their crops from roaming animals.

Profits are shared between the women and their husbands in the joint system as a sharecropping arrangement—men buy inputs for the next season. Women have the ability to manage their own plots, although this is often subject to the willingness of their husbands to provide support.

Access to irrigation technology

The choice of irrigation technology depends on land ownership, water source, land size, financial capacity of the individual and social support. Those with permanent land ownership rights are able to develop permanent irrigation infrastructure such as PSWs. Those who rent land invest in temporary structures, since some technologies are capital-intensive. Moreover, access to technologies differs between men and women. Women are not able to afford PSWs, unless their husbands decide to build the wells for them. Thus, PSWs are seen to fall under male prerogative. The RAD technology is labor-intensive, and men form mutual help groups to dig each other’s dugouts. Women, on the other hand, do not have the option of forming such groups since digging is done by men; they have to hire laborers.

Women tend to favor TSWs, which are suitable for relatively small plots and are less capital-intensive. They do not require hiring of labor, as much of the work is carried out by farmers and a water-lifting technology (with rope and bucket) is locally available and affordable. With TSWs, women are able to manage their plots, while performing their household duties at the same time.

Access to credit

Access to formal credit for irrigation development in the UER is poor, thus there is minimal difference in the access avail of between men versus women in terms of access to credit. Farmers try other options, such as borrowing from friends, selling their livestock or forming farmer groups to access bank loans. Here, the gender factor is evident. For instance, women are favored by banks and creditors because they are more reliable repayers of loans. Men encourage women to join cooperatives.
groups to obtain access to bank loans. This advantage is also one of the reasons women are participating in irrigation. High female participation has significantly increased access to credit.

Organized women’s groups

Organized women’s groups are located in major markets in Accra, Kumasi and in big cities in southern Ghana. They use trucks to transport vegetables. The irrigation group leaders lead the search for these markets. The women control the distribution. The leaders ensure that group members are served first before the non-members.

Conclusion

The use of irrigation technologies such as PSW, TSW, and RAD is a promising strategy to improve the livelihoods and well-being of the people in the UER of Ghana. To ensure the success of these interventions, it is important to look at the roles of both men and women in the construction and operation of irrigation infrastructure. The role of gender must also be identified in decision-making processes, cost-benefit analyses, gaining access (to land, water and markets), and defining in the social structure.
