Introduction

Little is documented on intra-household gender dynamics and locally specific gender norms that affect differential gender roles affecting:

- Management of cattle
- Adoption breeding technologies
- The choice of preferred breeds of cattle to rear

Methodology

Participatory and quantitative approaches were used to collate information from different categories of farmers in Camoapa Municipality of Boaco in Central Nicaragua.

Data disaggregated by the gender of the household head was collected over 8 months from 59 households on:

- The main breeds of cattle used for milk production on the farms
- Mating management practices in the cattle herd
- The daily Milk production by individual animals of different breeds

Summary statistics and analyses of variance were carried out using Genstat

Purpose

To evaluate impacts of intra-household gender influences on breed choice, productivity and the adoption of breeding technologies

Findings

Irrespective of the gender of the household head, Animals of all breed types are kept in milk beyond 365 days

Average daily milk production per animal was significantly lower (P<0.01) in female headed households than in male headed households

Farmers depend heavily on bulls either reared on their own farms or purchased from neighboring farms for mating. Only 10% of the households reported to have ever used Artificial Insemination.

Reasons for Low adoption of Artificial Insemination (AI)

1. Limited access to timely AI service, no semen storage facilities
2. Conception rates following use of AI are low
3. Detection of heat in cows served using AI is very poor
4. Few AI service providers, living long distances away from farms
5. Service of animals by bulls is relatively "free" while AI costs
6. Limited knowledge on AI procedures, no skills in heat detection. Use of AI creates dependency on external support which is undesirable

Conclusion

- There are real gender differences in access to and use of livestock breeding technologies in the farming systems of Camoapa
- A gendered approach in implementing breeding improvement programs is needed for equitable progress
